

Recovery Plan – Draft— Cotton leaf curl disease

Caused by Cotton leaf curl virus complex (Begomovirus, Geminiviridae): A whitefly-transmitted virus causing leaf curl disease of cotton, vegetable, and ornamental crops

Dr. Judith K. Brown
School of Plant Sciences
The University of Arizona
Tucson, Arizona USA

Economics of cotton

- Cultivated cotton *Gossypium* species (L.) have been a major source of food, feed and fiber worldwide for over 7000 years.
- Globally ~32.6 million hectares are devoted to cotton cultivation with production estimated at 27.6 million tons for 2011/2012 (Anonymous, 2011).
- Cotton is placed sixth on the *List of Economically Important Crops* for the U.S.

Virus-like disorders of cotton

Disease	Vector/Transmission	Geographical Distribution
Acromania	unknown	USA (Arizona), China, Haiti, Sudan
Cotton (common) yellow mosaic	<i>Bemisia tabaci</i>	Brazil
Cotton mosaic	<i>B. tabaci</i> unknown	Central America
Cotton leaf curl	<i>B. tabaci</i> grafting	USA (Louisiana)
Cotton leaf mottle	<i>Aphis gossypii</i>	Philippines
Cotton leaf roll /leaf curliness	<i>A. gossypii</i>	Sudan, USSR Thailand, Paraguay
Infectious variegation	grafting, <i>B. tabaci</i>	India
Indian leaf crumple	grafting, <i>B. tabaci</i>	India
Murcha vermelha /purple wilt	<i>B. tabaci</i>	South America
Terminal stunt	<i>A. gossypii</i>	USA (Texas)
Tobacco streak	possibly thrips	Brazil

Asia

- Cotton leaf curl Allahabad virus
- Cotton leaf curl Bangalore virus
- Cotton leaf curl Burewala virus
- Cotton leaf curl Kokhran virus
- Cotton leaf curl Multan virus
- Cotton leaf curl Rajasthan virus
- Cotton leaf curl Shadadpur virus

Cotton leaf curl Gezira virus: Proliferation of spongy parenchyma and bundle sheath extension cells, and hyperplastic cells (transverse sections) = Enations are a unique feature of OW leaf curl begomoviruses

BS: bundle sheath, BSE: bundle sheath extension, C: cuticle, CO: collenchyma cells, CU: leaf curvature or vein groove, LE: lower epidermis, LVS: secondary vein, UE: upper epidermis, P: phloem, S: stoma, SP: spongy parenchyma, X: xylem.

healthy

Cotton leaf curl disease (CLCuD) is a debilitating disease of cotton that results in leaf curling, development of leaf-like enations on the undersides of leaves, overall stunting of the plant, and reduced yield and quality.

-**CLCuD occurs** in Africa, Pakistan, and northwestern (Punjab region) India.

-Caused by **one or more whitefly-transmitted geminiviruses** (family *Geminiviridae*, genus *Begomovirus*) that serve as the 'helper virus' for to different kinds of DNA satellite molecules of non-viral origin: **betasatellites and alphasatellites**.

The satellites contribute to host defense suppression, leading to increased virulence of the helper virus that leads to systemic infection and severe disease symptoms; the promiscuity of the beta/alpha satellites may confer versatility to helper viruses.

-**The host range** of the CLCuD virus-satellite complexes has been found to be astoundingly broad, spanning multiple plant families, albeit, it was initially thought to be restricted to cotton and several wild malvaceous hosts.

Since 1990 Pakistan and India have experienced **two epidemics**:

- the most recent is the result of an emergent, **resistance breaking strain (2001-present)**

-overcame host-plant resistance in varieties developed to combat the first outbreak occurring in about 1990.

Brief history: Leaf curl viruses of cotton

1912-1960	Nigeria (1912- <i>G. barbadense</i>), Sudan (1924) –Leaf curl Gezira virus, Tanzania (1926), USA-CA/AZ leaf crumple virus (1951), Philippines (1959). In all instances - symptoms associated with whitefly <i>Bemisia tabaci</i> presence.
1967-1973	Leaf curl symptoms first reported in Pakistan in Multan, Punjab Provinces; by 1973 ‘Cotton leaf curl’ disease; Cotton leaf crumple occurs annually in cotton, US/Mexico.
1983-1993	CLCD outbreak in cotton near Multan –resulting in the first epidemic (80% incidence), spreading throughout Pakistan and into western India. The disease emerged again during 1989 and 1992-1994 (entire cotton belt).
1994-1999	Common Fund-Cotton project initiated with NIBGE (Zafar-NIBGE and Brown-UA); first effort to characterize the causal agent; identified a monopartite begomoviral genome and beta satellite complex. Cotton viruses in Sudan and American Tropics studied; causality proven for two main species (Brown et al) + Leaf curl in Pakistan. Breeding yielded resistant cotton varieties–production returned to pre-epidemic levels.
1997	Leaf curl symptoms reported in cotton fields in the Sindh Province.
2001	First appearance of resistance breaking in cotton in western India.
2001-2004	Evidence for more than one viral genome: <i>Cotton leaf curl Alalabad virus</i> (CLCuAV) and <i>Cotton leaf curl Khokhran virus</i> (CLCuKV); <i>Papaya leaf curl virus</i> (Mansoor et al., 2003b) and <i>Tomato leaf curl Bangalore virus</i> (Kirthi et al 2004); <i>Cotton leaf curl Rajasthan virus</i> in tomato and cotton India and Pakistan (Kirthi, Rehman, Shahid)
2009-12	All cotton varieties susceptible – tolerance in some lines; presence of a recombinant virus + Multan beta satellite : Cotton leaf curl Burewala virus (Amrao et al., 2010b) = parental viruses: CLCuMuV and CLCuKoV; subsequently spread to India = Current Project

Primary causal agents: Whitefly-transmitted geminiviruses

- **Family: Geminiviridae**
- **Genus: *Begomovirus***
- **Distributed worldwide**
- **Infect dicotyledonous hosts**
- **Monopartite begomoviruses - one circular ssDNA component ~2.8 kb**
- **Bipartite begomoviruses - two ss circular DNA components ~2.6 kb each**

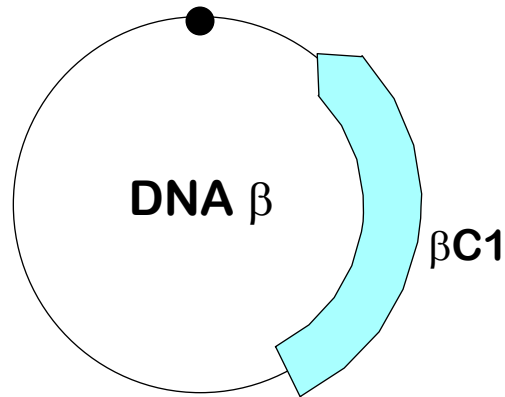

Particle Morphology

One ssDNA molecule per particle

DNA β
satellite

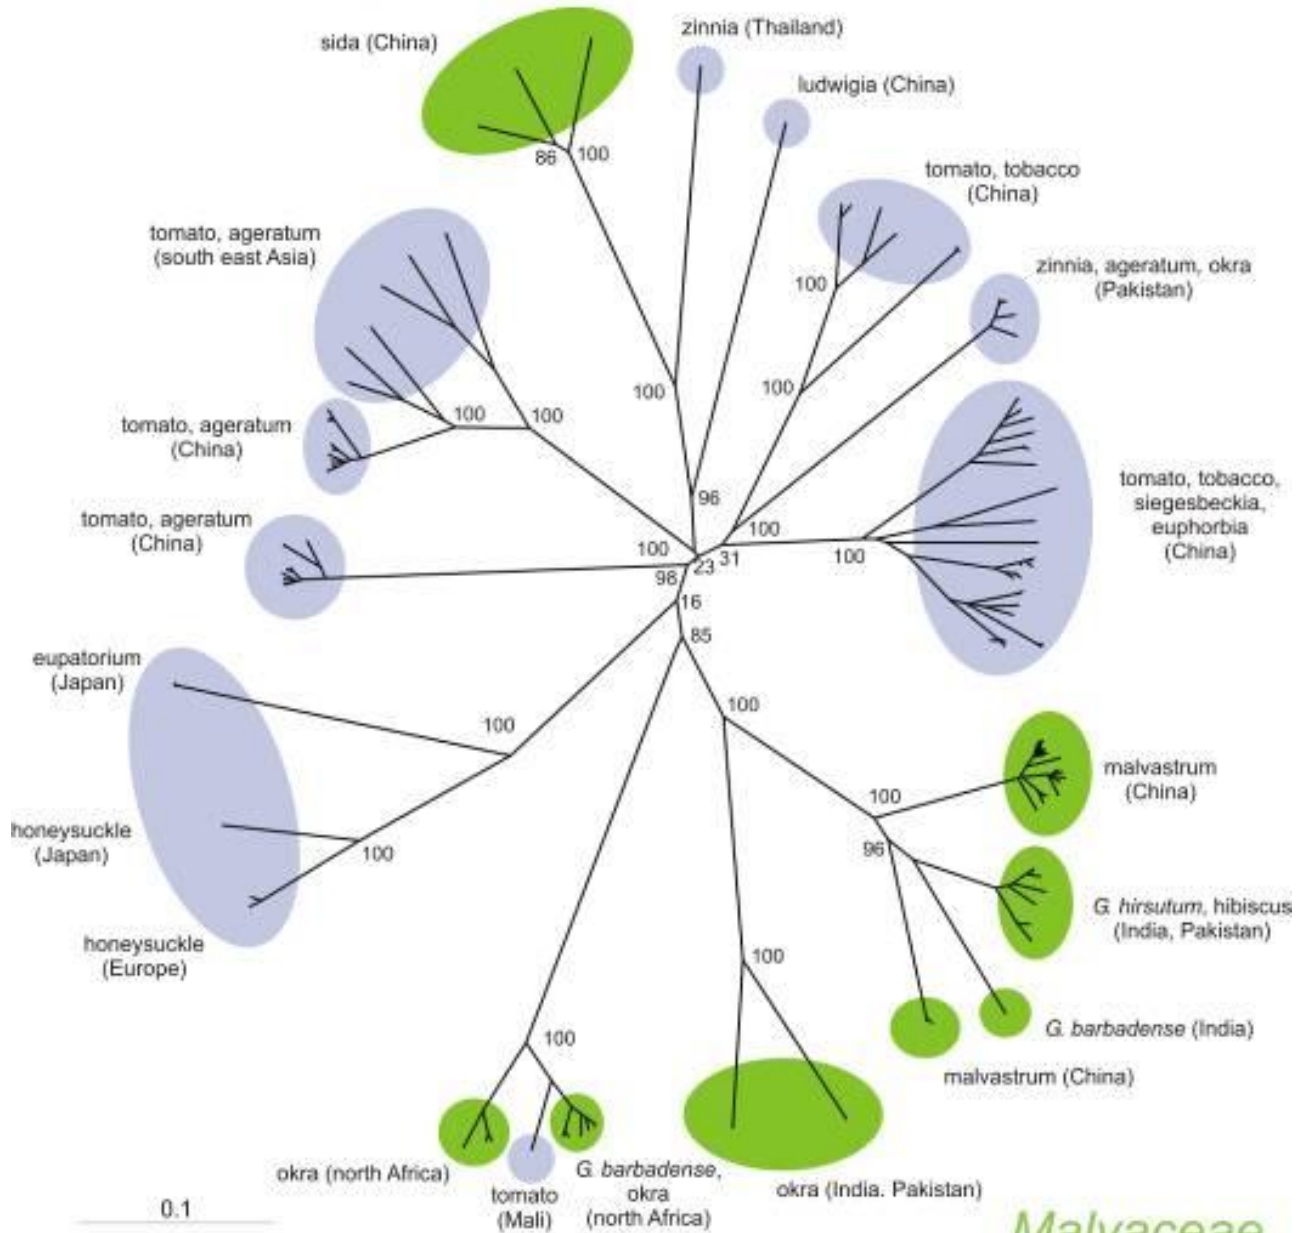

Structure of DNA β

- A single conserved ORF
- A region rich in adenine (approx. 300bp)
- A region conserved between all DNA β s (approx. 300bp)
- A hairpin structure (ori)

Properties of DNA β

- **Trans-replicated** by begomovirus encoded Rep
- **Requires helper** virus CP for transmission
- Essential for **symptom development** by helper virus
- **Enhances** helper **virus DNA accumulation**

non-Malvaceae

Malvaceae

The vector

Bemisia tabaci sibling species group

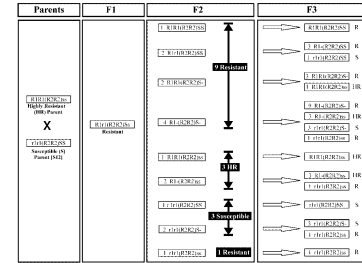

Characteristics

- Polyphagous insect (collectively, 500 host plant species)
- Haplodiploid reproduction
- Exclusively, phloem feeding
- Phylogenetically divergent mtCOI (0-26%)
- Variants referred to as haplotypes (mtCOI), or biotypes (mtCOI divergence + biological data)
- mtCOI phylogeographic distribution
- Causes billions of dollar losses annually worldwide
- Highly fecund
- Only insect vector, genus: *Begomovirus* (family, Geminiviridae)
- Recent examples invasive movement: TYLCV - worldwide owing to dispersal via ornamentals, seedlings, whitefly; *Cotton leaf curl virus*- Pakistan, India, China

Kingdom:	Animalia
Phylum:	Arthropoda
Class:	Insecta
Order:	Hemiptera
Family:	Aleyrodidae
Genus:	Bemisia
Species:	tabaci

Cotton leaf curl virus timeline

Resistance attributed to 3 genes: two R genes and “suppressor”

1967 **First report**

Sporadic isolated infections of cotton

Start of the CLCuV epidemic

Introduction of resistant varieties late 1990s

1988

Introduction of an American cotton variety (S12)

Resistance breaking

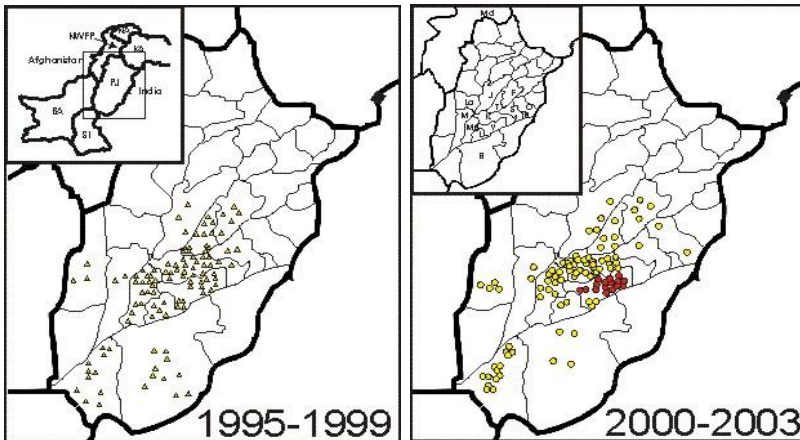

\$5 billion losses from 1992-1997 due to CLCuD

2001

Second Epidemic:

recombinant Bur virus + CLCuMB

Courtesy R. Briddon)

The “Multan” strain of CLCuD

- *Cotton leaf curl Multan virus*
- *Cotton leaf curl Kokhran virus*
- *Papaya leaf curl virus*
- *Tomato leaf curl Karnataka virus*
- *Cotton leaf curl Alabad virus*
- *Cotton leaf curl Rajasthan virus*
- *Cotton leaf curl Bangalore virus*

- **One betasatellite (CLCuMB)**

- Pre-resistance breaking - 7 viruses one betasatellite
- **Post -resistance breaking - 1 virus one betasatellite**

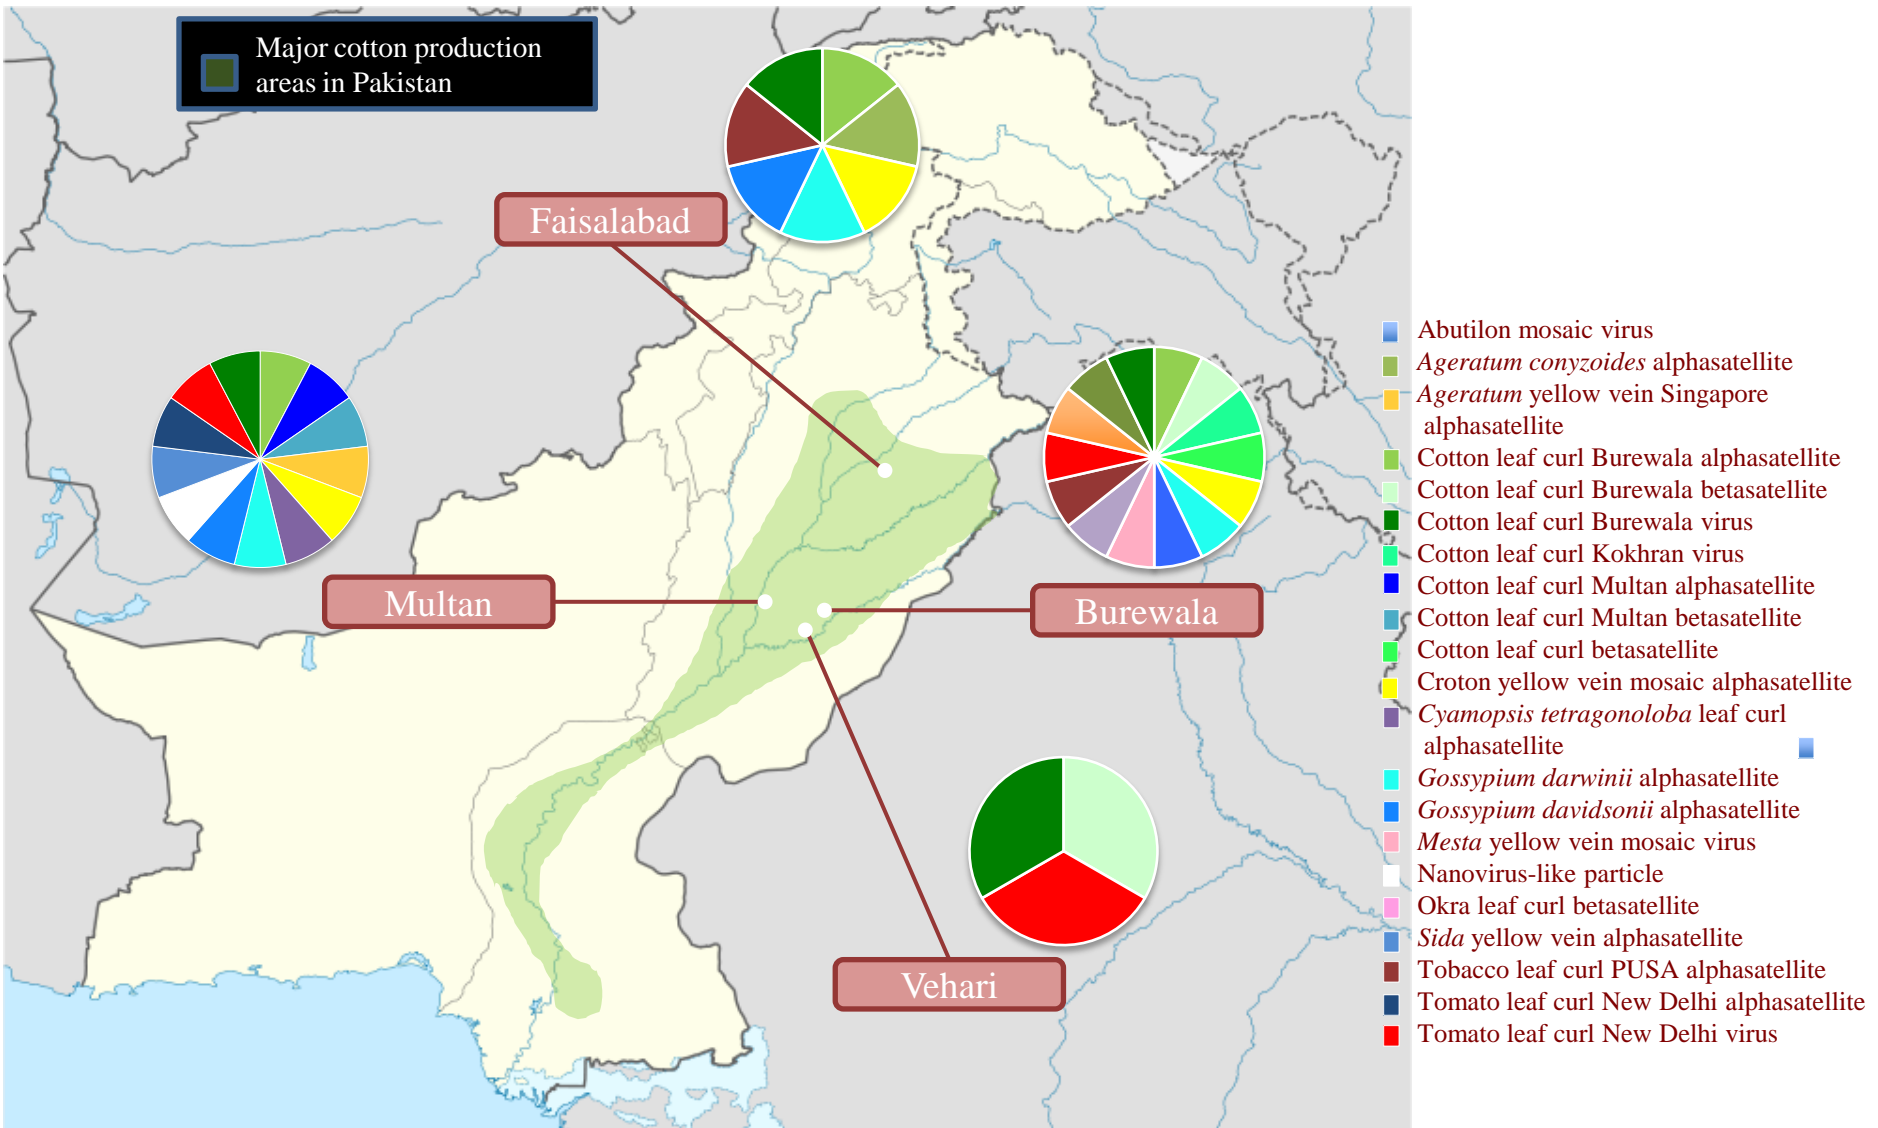

Disease Severity Ratings 0-4

Estimated losses due to CLCVD

Year of infestation	Estimated crop damage			Estimated Financial Losses	
	(Partial)	(Complete)	(Total)	(Mill.Bales)	(Bill.PKR)
2006-07	1686.40	25.21	1711.63	1.23	14.063
2007-08	1432.80	2.50	1435.29	0.95	13.778
2008-09	1440.10	40.25	1480.35	1.11	16.079
2009-10	1693.50	43.39	1956.62	1.84	44.160
2010-11	1341.80	28.33	1370.12	1.16	48.457
2011-12	569.60	0.00	569.60	0.48	11.815

Virus detection to populations.....

- Entire venue for virus detection and identification of species and variants has evolved from:
- No molecular techniques to -DNA hybridization – to Polymerase chain reaction to - genome sequencing –Rolling circle amplification –to New Generation sequencing
- Enables high throughput vs single samples
- Facilitating views of diversification and population structure in a new light

from....PCR strategies for ID & diversity studies

core Cp

quick ID: universal primers & determine seq in a single run (576-579 bp)

full CP

1.1 kbp fragment; two sequencing rxns; provisional ID and relationships = DNA-A)

+

2/3 DNA-A overlap w/ CP

CP & CR

(2.1 kbp)

Top Half B

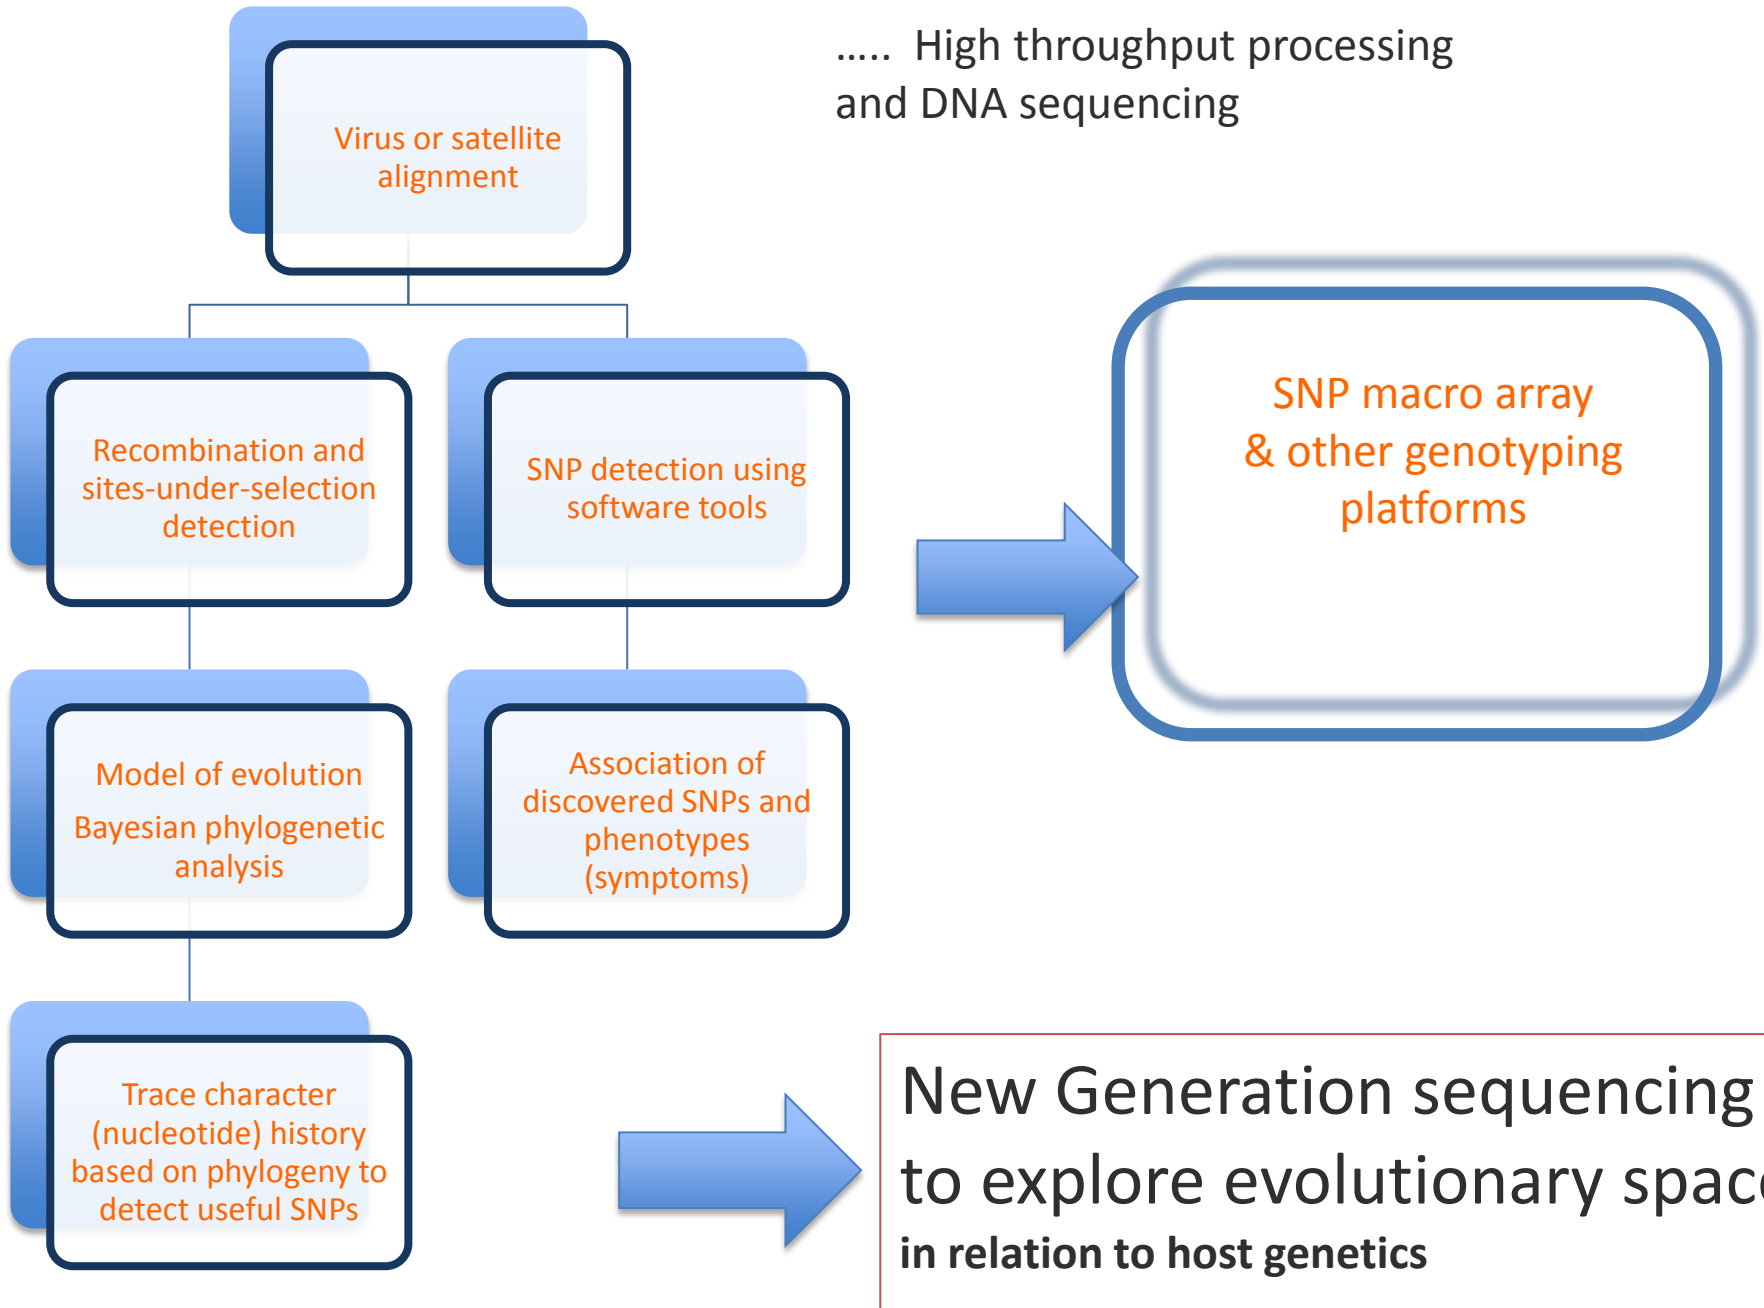

CR - cognate component (1.5 kbp)

= DNA-A Cloning sites

to..

..... High throughput processing and DNA sequencing

Virus or satellite alignment

Recombination and sites-under-selection detection

SNP detection using software tools

Model of evolution
Bayesian phylogenetic analysis

Association of discovered SNPs and phenotypes (symptoms)

Trace character (nucleotide) history based on phylogeny to detect useful SNPs

SNP macro array & other genotyping platforms

New Generation sequencing to explore evolutionary space in relation to host genetics

Global Concerns:

- Spread of diverse species to cotton-growing regions and widespread losses could create a global economic crisis and shortage of supply
- CLCuMV and satellite already found in China-moved on ornamental plants
- Invasive whitefly biotypes, also Re-distributed via trade
- Further threat due to high diversity / broad host range

THE UNIVERSITY

Thank you

Phylogeny of OW begomoviruses infecting cotton, hollyhock, and okra

Alphasatellites

Enations (box) developing on a main vein of cotton leaf inoculated with CLCuGV and sat DNA - 'vein thickening'

Swelling of veins results from proliferation of spongy parenchyma and bundle sheath cells, with SP being more swollen than bundle sheath cells.

This asymmetric proliferation of veins causes the formation of veinal grooves.

Transverse sections of cells associated with enations that form on CLCuGV-infected leaves contain parenchyma instead of collenchyma with very thin cell walls.
