We thank A. H. Fielding for his gift of p-nitrophenyl α-l-arabino-furanosidase.

Accepted for publication 2 February 1979.

**ABSTRACT**

*Sclerotinia sclerotiorum* produced α-l-arabino-furanosidase when grown at 25°C on a medium of mineral salts containing 0.4% 1-arabinose plus 0.2% Difco yeast extract. Enzyme in filtrates from 14-day-old cultures was concentrated and dialyzed by Amicon ultrafiltration. The specific activity of the α-l-arabino-furanosidase was increased 26× by a four-step procedure: (i) preparative electrofocusing in granulated gel using ampholytes with a pH of 7–9; (ii) column ion-exchange chromatography (CM-Sephadex [C-50]) in 20 mM sodium acetate at pH 5.0; and (iii, iv) two cycles of gel filtration on Ultrogel (AcA 54) in 72 mM phosphate buffer at pH 7.0 containing 100 mM NaCl. Purified α-l-arabino-furanosidase had a pH optimum of 4.0–4.5, a molecular weight of about 63,000 and a pl of about 7.5. This enzyme released arabinose from arabinan from isolated cell walls and from intact cell walls of bean and rice. Highly active preparations of this α-l-arabino-furanosidase failed to macerate potato tuber or cucumber endocarp tissue.

Decomposition of cell walls during tissue invasion and pathogenesis is a characteristic feature of numerous plant diseases incited by facultative, necrotrophic pathogens. The role of pectic enzymes in tissue maceration, cell wall disruption, and cell lysis is now generally appreciated (7,23). The involvement of cellulases, galactanases, xyloganases, and arabinase in pathogenesis is less well understood. Many pathogens produce enzymes during pathogenesis, however, and in many instances, their substrates in the invaded hosts are degraded (2,6-8,18).

The significance of enzymes that digest structural polysaccharides in the plant cell wall remains to be elucidated with respect to pathogen ingress. How important are they in this process? Do these enzymes play an essential role in pathogen ramification of host tissues? Before these questions can be adequately approached experimentally, we need to understand better the precise chemical structure of the plant cell wall, as well as the involvement of polysaccharides in cell wall disruption. The availability of purified enzymes that attack each of the major glycosidic linkages in cell walls is essential for the studies needed to answer the above questions.

Several reports have concerned the purification of arabinosidase from various sources (10–13,17). However, the purity of these preparations in regard to trace amounts of other cell wall-degrading enzymes has not been sufficiently demonstrated.

We previously reported source organisms and procedures for purifying endopeptidase (5), endo-β-1,4 galactanase (9), and endo-β,1,4 xylanase (4). Here we report the purification and characterization of αααα-l-arabino-furanosidase produced by *Sclerotinia sclerotiorum* and some of its effects on isolated cell walls and on excised potato tuber and cucumber endocarp tissues.

**MATERIALS AND METHODS**

**Substrates and chemicals.** The p-nitrophenyl α-l-arabino-furanosidase was a gift from A. H. Fielding, Long Ashton Research Station, Bristol, U.K. The arabinan, galactan, xylan, polygalacturonic acid, carboxymethylcellulose, and mannan used as potential enzyme substrates were the same as those used by Baker et al (4). l-arabino-l, 4-lactone was purchased from Koch-Light Lab., Ltd., Colnbrook, U.K. D-galactono-l, 4-lactone, D-

The water and buffer washes from each column were combined and assayed for α-L-arabinofuranosidase, polygalacturonase, and galactanase activities.

Fractions containing α-L-arabinofuranosidase activity were pooled, dialyzed against 20 mM sodium acetate buffer at pH 5.0, and applied to a 1.5 x 20 cm CM-Sephadex (C-50) ion-exchange column equilibrated with the same buffer. The column was eluted at a flow rate of 12 ml/hr with a 200-m1 linear salt gradient in buffer (0–100 mM NaCl). Five-milliliter fractions were collected and assayed for α-L-arabinofuranosidase, galactanase, and polygalacturonase. The peak fractions of α-L-arabinofuranosidase were pooled and concentrated by ultrafiltration. The enzyme concentrate was applied to an Ultrogel (Aca 54) gel filtration column (2.5 x 70 cm), equilibrated with 72 mM phosphate buffer at pH 7.0 containing 100 mM NaCl. The column flow rate was adjusted to 15 ml/hr and 2-m1 fractions were collected and then assayed for α-L-arabinofuranosidase, galactanase, and polygalacturonase. Reaction mixtures for the latter two enzymes were allowed to incubate 2 hr before assaying. The fractions that degraded galactan were subjected to paper chromatography to distinguish release of glucose and galactose oligomers from release of arabinose. Fractions containing only α-L-arabinofuranosidase activity were pooled. In some cases, the gel filtration step had to be repeated, using the pooled α-L-arabinofuranosidase fractions, in order to free this enzyme from polygalacturonase and/or galactanase.

The molecular weight of the purified α-L-arabinofuranosidase was estimated by sucrose density-gradient ultracentrifugation (22) and SDS discontinuous gel electrophoresis (4). The reference compounds (and their molecular weights) used in the sucrose density-gradient studies were: cytochrome C (12,300), horseradish peroxidase (40,000), and human γ-globulin (153,100). Lysozyme (14,300), soybean trypsin inhibitor (21,000), carbonic anhydrase (30,000), ovalbumin (45,000), bovine serum albumin (68,000), and phosphorylase B (94,000) were used as references in the SDS gel electrophoretic studies. Low-pH gel electrophoresis (4) was used to study homogeneity of the purified enzyme.

RESULTS

Purification and characterization of α-L-arabinofuranosidase from S. sclerotiorum. The α-L-arabinofuranosidase activity in crude culture filtrates of S. sclerotiorum, grown at 25°C on a mineral salts medium supplemented with 0.4% arabinose, increased over a 19-day culture period. This enzyme was purified from 14-day-old culture filtrate (2,653 ml) that contained 0.136 units of α-L-arabinofuranosidase activity per milliliter (Table 1).

Narrow pH range electrofocusing (pH 7.0–9.0) of crude dialyzed enzyme concentrate showed that the α-L-arabinofuranosidase had a pH of 7.5 and could be resolved from a minor peak of polygalacturonase (pH 4.7) and galactanase (pH 8.0) (Fig. 1). The apparent galactanase activity associated with the α-L-arabinofuranosidase peak occurred primarily because of the release of arabinose from the galactan substrate (Table 2). In this particular assay, therefore, only the presence of galactose in the reaction mixture was taken as evidence for galactanase activity.

In the next purification step, the peak α-L-arabinofuranosidase fractions were applied to a CM-Sephadex column and eluted at about 30 mM NaCl (Fig. 2). This procedure further resolved the α-L-arabinofuranosidase from polygalacturonase that eluted at 45 mM NaCl. Paper chromatography of reaction products revealed that arabinose was released from lupin galactan by fractions containing α-L-arabinofuranosidase, and galactose and oligomers of galactose were released by fractions following the α-L-arabinofuranosidase peak (Fig. 2).

The remaining traces of polygalacturonase and galactanase associated with the α-L-arabinofuranosidase peak eluted from the

* Calculated activity based on assays of reaction mixtures incubated for 1 hr.

* Reaction products were monomeric arabinose by paper chromatography.

* PNP = p-nitrophenol.

* Calculated activity based on assays of reaction mixtures incubated for 10 min.
CM-Sephadex (C-50) column were removed by two cycles of Ultrogel (AcA 54) gel filtration in 72 mM phosphate buffer at pH 7.0 containing 100 mM NaCl (Fig. 2). In this system, polygalacturonase preceded, and galactanase followed, the elution of \( \alpha \)-l-arabinofuranosidase. This purification procedure resulted in a 26-fold increase in the specific activity of the \( \alpha \)-l-arabinofuranosidase and a 5% recovery (Table 1). The purified enzyme was stored at \(-20^\circ\)C in 50 mM sodium acetate buffer at pH 5.0 containing 100 mM NaCl and 0.02% sodium azide for up to 1 yr without significant loss of activity.

Low-pH, discontinuous gel electrophoresis of 2–34 \( \mu \)g of the purified enzyme revealed a single diffuse protein band when the gels were stained with Coomassie Brilliant Blue R. This band coincided with the location of \( \alpha \)-l-arabinofuranosidase activity eluted from nonstained gels. SDS electrophoresis of 9.5 \( \mu \)g of the purified enzyme revealed a single protein with a molecular weight of 62,000; the molecular weight estimated by sucrose density-gradient ultracentrifugation was 64,000. When 19 or 38 \( \mu \)g of enzyme was subjected to SDS gel electrophoresis, the stained gel revealed a faint protein band that migrated slightly ahead of the major band. The pH optimum for the hydrolysis of PNP-\( \alpha \)-l-arabinofuranoside by the purified enzyme was between pH 4.0 and 4.5 when determined in 50 mM sodium citrate-50 mM potassium phosphate buffer (pH 3.7) or in 50 mM sodium acetate buffer (pH 3.5–5) (Fig. 4). When 0.2 units of enzyme per milliliter were incubated with 0.1% arabinbin in 50 mM sodium acetate buffer at pH 4.5, the only product detected by paper chromatography (4) was arabinose. Chromatograms were prepared after 0, 5, 8, 5, 9, and 16% hydrolysis of the arabinan substrate as determined by the release of reducing groups. When similar reaction mixtures contained PNP glycosides or various polysaccharides, no reducing groups or hydrolytic products were detected except for the reaction mixtures containing lupin galactan (Table 2). The product released from this substrate was arabinose. Hydrolysis of PNP-\( \alpha \)-l-arabinofuranoside by the purified enzyme was inhibited 70% and 24%, respectively, by 1.48 mM laranbinolactone and 1.48 mM D-galactoolactone. Neither D-glucurononate nor D-mannoolactone inhibited this enzyme.

**Effects of \( \alpha \)-l-arabinofuranosidase on isolated plant cell walls and tissues.** The ability of the purified \( \alpha \)-l-arabinofuranosidase to solubilize constituents of isolated bean and rice cell walls was examined (Table 3). The carbohydrates in the supernatants from buffer (control) and enzyme treatments were hydrolyzed by

![Fig. 4. Hydrolysis of p-nitrophenyl-\( \alpha \)-l-arabinofuranoside by purified \( \alpha \)-l-arabinosidase from *Sclerotinia sclerotiorum* in relation to pH at 30 C in 50 mM buffers.](image3)
trifluoroacetic acid (TFA) and analyzed by gas chromatography for neutral sugars using the procedures of Albersheim et al (3).

Only traces of arabinose, mannose, galactose, and glucose were detected in the supernatant of control reaction mixtures containing either bean or rice cell walls. The supernatant of bean walls treated with α-L-arabinofuranosidase contained traces of mannose and glucose plus 2.38 and 0.38% of the cell wall weight as arabinose and galactose, respectively. The number and quantities of sugars released by the enzyme from rice cell walls and bean cell walls were similar (Table 3). The enzyme released 20.7% and 13.8%, respectively, of the arabinose in bean and rice cell walls as determined by TFA hydrolysis of buffer-treated cell walls.

The potential for α-L-arabinofuranosidase to macerate plant tissue was examined in reaction mixtures containing 0.26 units of α-L-arabinofuranosidase per milliliter, six tissue discs (9×0.5 mm) of potato tuber tissue or cucumber endocarp tissue, and 0.02% sodium azide in a 3-ml volume of 50 mM sodium acetate buffer at pH 5.0. Controls consisted of reaction mixtures without enzyme and reaction mixtures containing 0.3 units of endopectate lyase (5) instead of α-L-arabinofuranosidase. Reaction mixtures were incubated for up to 24 hr at 25 C and examined periodically for tissue maceration (22). The purified α-L-arabinofuranosidase did not macerate either plant tissue during these experiments. The endopectate lyase completely macerated the potato and cucumber tissue discs within 1 hr. Assay of reaction mixtures for α-L-arabinofuranosidase activity after 24-hr incubation showed that 90% of the initial enzyme activity was present.

**DISCUSSION**

*S. sclerotiorum* produced α-L-arabinofuranosidase and galactanase plus smaller amounts of polygalacturonase when cultured on a medium containing 0.4% L-arabinose as the carbon source. Cultures of *Verticillium albo-atrum* and *Fusarium oxysporum* behave in a similar manner when grown on low concentrations of L-arabinose (14).

A large number of plant pathogenic fungi produce α-L-arabinofuranosidas (10,12,16,18,24). The cell walls in hosts invaded by some of these pathogens lose cell wall arabanose during pathogenesis (8,18). In addition, the virulence of *S. fructigena* isolates correlates with their ability to produce α-L-arabinofuranosidase (19). The role and significance of this enzyme in plant cell wall decomposition or pathogenesis remains to be determined, however. There are conflicting reports about the ability of α-L-arabinofuranosidase to cause plant tissue maceration (10-13,17). These reports may conflict owing to the presence of pectic enzymes in some of the α-L-arabinofuranosidase preparations used in tissue maceration studies. The α-L-arabinofuranosidas from *S. rossellii* (12) and *Penicillium digitatum* (13) both failed to macerate plant tissues when freed of polygalacturonase. The α-L-arabinofuranosidase of *S. sclerotiorum* purified in this study also failed to macerate either potato or cucumber tissue.

The properties of the purified α-L-arabinofuranosidase from *S. sclerotiorum* were quite similar to those of α-L-arabinofuranosidas produced by a number of other plant pathogenic fungi (15,16,24), except for its pl, which is about pH 7.5; those reported for other fungal α-L-arabinofuranosidas range from pH 3.0 to 6.5 (15).

The α-L-arabinofuranosidase of *S. sclerotiorum* was inhibited in a competitive manner by L-arabinose-1,4-lactone and D-galactono-1,4-lactone but not by D-glucono-1,5-lactone or D-mannono-1,4-lactone. The α-L-arabinofuranosidas from *Phytophthora palmivora* and *S. fructigena* responded similarly to these compounds (1,20).

Only L-arabinose was released from arabamin or lupin galactan by the purified α-L-arabinofuranosidase produced by *S. sclerotiorum*. This enzyme released only 16% of the arabmin in beet arabamin, which suggests that this enzyme is either specific for certain bonds in the substrate or that the presence of branches in the substrate and/or the occurrence of anomalous sugars within the arabamin chain block further action of this enzyme. An α-L-arabinofuranosidase from *Aspergillus niger* has been reported to release about 90% of the arabmin in beet arabamin (26). The quantity and pattern of release of arabmin from arabamin by the α-L-arabinofuranosidase of *S. sclerotiorum* resembled that reported for a similar enzyme produced by *Sclerotium rolfsii* (12).
